Slide Title — Patterns of Major Economic Indicators

“To clearly understand the outcomes of Argentina’s populist model and Chile’s neoliberal reforms,

we need to look beyond theory and focus on indicators that show real life effects.

So I will compare four major economic indicators:

GDP growth, inflation and debt, inequality, and poverty or living conditions.”

Slide — Indicator Comparison

GDP Growth:

“Chile has maintained steady long-term growth, because its core economic rules remain stable.

This attracts investment and creates predictable opportunities. Meanwhile, Argentina shows rapid growth followed by deep recession,

because economic policy changes frequently from government to government.”

- Chile averaged about **4–5%** growth after the 1990s.
- Argentina’s growth swings a lot, sometimes **–10%** during crises.

Inflation & External Debt

“In Argentina, inflation directly affects daily life —

salaries lose value fast, and saving money becomes almost impossible.

This repeated inflation has also increased external debt. Chile controlled inflation earlier through independent monetary policy,

allowing families and businesses to make long-term financial decisions.”

- Argentina has had inflation above **50%** many recent years.
- Chile kept inflation around **3%** after the 1990s.

Inequality — Gini Index

“Chile grew faster as a country, but wealth concentrated at the top. Many people felt excluded even during economic success, which contributed to the 2019 protests. In Argentina, inequality is generally lower, but economic instability destroys progress again and again.”

- Chile’s Gini index has stayed **0.45+**, meaning high inequality.
- Argentina is lower, around **0.35–0.40**.

Poverty & Social Conditions

“Chile reduced poverty more successfully, mainly because growth was stable. But high inequality means many citizens feel their improvement is limited. Argentina expanded welfare to support the poor, yet recurring crises push people back into poverty repeatedly.”

- Chile reduced poverty from around **40%** → **under 10%**.
- Argentina often improves but falls back during crisis years.

Final Impact Message

“So, the data reveals a clear contradiction:

- Chile shows stability without enough fairness
- Argentina shows fairness without enough stability

This comparison teaches that economic development must balance both — stable institutions that prevent crisis, and social inclusion that ensures progress benefits everyone.”
